# Lake Model: Workers' Dynamics and Markov Process

Quantitative Economics with Python

New York University

Tuesday 22<sup>nd</sup> March, 2016

#### Overview

- A worker's employment dynamics are governed by a Markov process
- The worker can be in one of two states:
  - $\circ$  s=0 means that the worker is unemployed
  - $\circ$  s=1 means that the worker is employed
- The transition matrix between the two states

$$P_{ij} = \mathsf{Prob}(s_{t+1} = j | s_t = i)$$

and

$$P = \begin{pmatrix} 1 - \alpha & \alpha \\ \lambda & 1 - \lambda \end{pmatrix}$$

ullet  $P_{ij}$ : probability for worker moves from state i at t to state j at t+1

#### Questions

- What is the average fraction of time a worker being employed over time?
- What is the fraction of workers who are employed at a particular time?
- What is the link between the answers to the above questions?

To answer these questions, we need some knowledge about Markov chain.

#### **Finite Markov Chains**

- Stochastic Matrix and Markov Chain
  - Definition
  - Irreducibility
  - Aperiodicity
- Marginal Distribution
  - Definition
  - Evolution of marginal distribution
  - Stationary marginal distribution
  - Unique stationary distribution
- Ergodicity

## Stochastic Matrix (Markov Matrix)

- Let  $S = \{s_1, s_2, \dots, s_n\}$
- $\bullet$  A stochastic matrix is an  $n\times n$  square matrix P=P[s,s'] such that
  - $_{\circ}\,$  each element P[s,s'] is nonnegative, and
  - $\circ$  each row  $P[s,\cdot]$  sums to one
- ullet Each row  $P[s,\cdot]$  can be regarded as a distribution on S
- ullet Remark: if P is a stochastic matrix, so is k-th power  $P^k$  for all  $k\in\mathbb{N}$

## Stochastic Matrix: Example

• Let's look at the worker's employment dynamics example

$$P = \begin{pmatrix} 1 - \alpha & \alpha \\ \lambda & 1 - \lambda \end{pmatrix}$$

- All elements are positive
- Each row sums to one

### Stochastic Matrix: Example

• Stochastic matrix about U.S. economy state (monthly frequency)

$$P = \left(\begin{array}{ccc} 0.971 & 0.029 & 0\\ 0.145 & 0.778 & 0.077\\ 0 & 0.508 & 0.492 \end{array}\right)$$

- o the first state represents "normal growth"
- the second state represents "mild recession"
- o the third state represents "severe recession"
- For example, when the state is normal growth, the state will again be normal growth next month with probability 0.97
- Large values on the main diagonal indicate persistence in the process

## Stochastic Matrix: Multiple Step Transition Probability

- ullet The probability of transitioning from s to s' in m step:  $P^m[s,s']$ .
- A two state example

$$P = \begin{pmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{pmatrix}$$

- ullet Probability of moving from state i to state j in one period is  $p_{ij}$
- Probability of moving from state 1 to state 1 in two periods is

$$\begin{pmatrix} p_{11}p_{11} + p_{12}p_{21} & p_{11}p_{12} + p_{12}p_{22} \\ p_{21}p_{11} + p_{22}p_{21} & p_{21}p_{12} + p_{22}p_{22} \end{pmatrix} = P \times P = P^2$$

#### Markov Chain

ullet A Markov Chain  $\{X_t\}$  is a stochastic process that has the Markov property

$$\mathbb{P}\{X_{t+1} = s' \mid X_t\} = \mathbb{P}\{X_{t+1} = s' \mid X_t, X_{t-1}, \ldots\}$$

- Knowing current state is enough to understand probabilities for future states
- The dynamics of a Markov chain are fully determined by the set of values

$$P[s, s'] = \mathbb{P}\{X_{t+1} = s' \mid X_t = s\} \qquad (s, s' \in S)$$

- $\circ$  P[s,s'] is the probability of going from s to s' in one unit of time (one step)
- $_{\circ}\ P[s,\cdot]$  is the conditional distribution of  $X_{t+1}$  given  $X_{t}=s$
- $\bullet$  It's clear that P is a stochastic matrix

#### Markov Chain

- ullet With a stochastic matrix P, we can generate a Markov chain  $\{X_t\}$ 
  - $\circ$  draw  $X_0$  from some specified distribution
  - $\circ \ \, \mathsf{draw} \,\, X_{t+1} \,\, \mathsf{from} \,\, P[X_t, \cdot]$
- Let us move to Python to generate some...

### Irreducibility

- Let P be a fixed stochastic matrix
- ullet Two states s and s are said to communicate with each other if there exist positive integers j and k such that

$$P^{j}[s, s'] > 0$$
 and  $P^{k}[s', s] > 0$ 

- This means that
  - $\circ$  state s can be reached eventually from state s'
  - $\circ$  state s' can be reached eventually from state s
- ullet The stochastic matrix P is called irreducible if all states communicate

## Irreducibility

• Worker's employment dynamics example is irreducible

$$P = \begin{pmatrix} 1 - \alpha & \alpha \\ \lambda & 1 - \lambda \end{pmatrix}$$

ullet Suppose worker has probability d to die

$$P = \begin{pmatrix} (1-d)(1-\alpha) & (1-d)\alpha & d\\ (1-d)\lambda & (1-d)(1-\lambda) & d\\ 0 & 0 & d \end{pmatrix}$$

This is not irreducible. Death is an absorbing state.

### **Aperidocity**

 Loosely speaking, a Markov chain is called periodic if it cycles in a predictible way and aperiodic otherwise

$$P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

 $\bullet$  The period of a state s is the greatest common divisor of the set of integers

$$D(s) := \{ j \ge 1 : P^{j}[s, s] > 0 \}$$

 A stochastic matrix is called aperiodic if the period of every state is 1, and periodic otherwise

## **Aperidocity**

Consider the following example

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 0.5 & 0 & 0.5 \\ 0 & 1 & 0 \end{pmatrix}$$

All the states have period 2, which is a periodic Markov chain.

• Consider the following example

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 0.5 & 0 & 0.5 \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

All the states have period 1, which is a aperiodic Markov chain.

### **Marginal Distribution**

- Suppose that
  - $\circ~\{X_t\}$  is a Markov chain with stochastic matrix P
  - $_{\circ}\,$  the distribution of  $X_{t}$  is known to be  $\psi_{t}$
- What is the distribution of  $X_{t+1}$ , or, more generally, of  $X_{t+m}$ ?

### **Marginal Distribution**

- Let  $\psi_t$  be the distribution of  $X_t$ . We are looking for  $\psi_{t+1}$  given  $\psi_t$  and P
- To begin, pick any  $s' \in S$ . The probability that  $X_{t+1} = s'$  is:

$$\mathbb{P}\{X_{t+1} = s'\} = \sum_{s \in S} \mathbb{P}\{X_{t+1} = s' \mid X_t = s\} \cdot \mathbb{P}\{X_t = s\}$$

- We account for all ways this can happen and sum their probabilities.
- More compactly

$$\psi_{t+1}[s'] = \sum_{s \in S} P[s, s'] \psi_t[s]$$

ullet There are n such equations, and the matrix expression is

$$\psi_{t+1} = \psi_t P$$

### **Marginal Distribution**

- $\bullet$  To move the distribution forward one unit of time, we postmultiply by P
- ullet By repeating this m times we move forward m steps into the future
- Hence,  $\psi_{t+m} = \psi_t P^m$  is also valid
- If  $\psi_0$  is the initial distribution from which  $X_0$  is drawn, then  $\psi_0 P^m$  is the distribution of  $X_m$

$$X_0 \sim \psi_0 \implies X_m \sim \psi_0 P^m$$

$$X_t \sim \psi_t \implies X_{t+m} \sim \psi_t P^m$$

## **Stationary Distribution**

• A distribution  $\psi^*$  is called stationary for P if  $\psi^* = \psi^* P$ 

#### Theorem

Every stochastic matrix P has at least one stationary distribution

#### **Theorem**

If P is irreducible and aperiodic, then

- P has a unique stationary distribution
- ② For any initial distribution  $\psi_0$ ,  $\|\psi_0 P^t \psi^*\| \to 0$  as  $t \to \infty$

## **Ergodicity**

• Under irreducibility, for all  $s \in S$ ,

$$\frac{1}{n} \sum_{t=1}^{n} \mathbf{1}\{X_t = s\} \to \psi^*[s] \quad \text{as } n \to \infty$$

- $\mathbf{1}{X_t = s} = 14$  if  $X_t = s$  and zero otherwise
- o convergence is with probability one
- $\circ$  the result does not depend on the distribution (or value) of  $X_0$
- $\bullet$  The fraction of time the chain spends at state s converges to  $\psi^*[s]$  as time goes to infinity
